Nutrient Management Module No. 9

Plant Nutrient Functions and Deficiency and Toxicity Symptoms

by Ann McCauley, Soil Scientist; Clain Jones, Extension Soil Fertility Specialist; and Jeff Jacobsen, College of Agriculture Dean

Introduction
This module is the ninth in a series of extension materials designed to provide extension agents, Certified Crop Advisers (CCAs), consultants, and producers with pertinent information on nutrient management issues. To make the learning ‘active,’ and to provide credits to CCAs, a quiz accompanies this module. In addition, realizing that there are many other good information sources including previously developed extension materials, books, web sites, and professionals in the field, we have provided a list of additional resources and contacts for those wanting more in-depth information about plant nutrient functions and deficiency and toxicity symptoms.

Objectives
After reading this module, the reader should be able to:

1. Identify and diagnose common plant nutrient deficiency and toxicity symptoms
2. Know potential limitations of visual diagnosis
3. Understand how to use a key for identifying deficiency symptoms
4. Distinguish between mobile and immobile nutrient deficiencies
Background

Discussed in *Nutrient Management Module 2, Plant Nutrition and Soil Fertility*, plants require essential nutrients for normal functioning and growth. A plant’s sufficiency range is defined as the range of nutrient necessary to meet the plant’s nutritional needs and maximize growth (Figure 1). The width of this range will depend upon individual plant species and the particular nutrient. Nutrient levels outside of a plant’s sufficiency range will cause overall crop growth and health to decline due to either a deficiency or toxicity. Nutrient deficiency occurs when an essential nutrient is not available in sufficient quantity to meet the requirements of a growing plant. Toxicity occurs when a nutrient is in excess of plant needs and decreases plant growth or quality. Common nutrient deficiencies in Montana and Wyoming are nitrogen (N) and phosphorus (P), with some deficiencies of potassium (K), sulfur (S), boron (B), chloride (Cl), copper (Cu), iron (Fe), manganese (Mn), and zinc (Zn). Micronutrient deficiencies are fairly uncommon with deficiencies of B, Cl, Fe, and Zn occurring most often (*Nutrient Management Module 7, Micronutrients: Cycling, Testing and Fertilizer Recommendations*). Nutrient toxicity is less common than deficiency and most likely occurs as a result of the over-application of fertilizer or manure.

The three basic tools for diagnosing nutrient deficiencies and toxicities are 1) soil testing; 2) plant analysis; and 3) visual observations in the field. Both soil testing (*Nutrient Management Module 1, Soil Sampling and Laboratory Selection*) and plant analysis (Q&A #1 and #2) are quantitative tests that are compared to the sufficiency range for a particular crop. Visual observation, on the other hand, is a qualitative test and is based on symptoms such as stunted growth or a yellowing of leaves occurring as a result of nutrient stress. This module focuses on visual nutrient deficiency and toxicity symptoms observed in common crops grown in Montana and Wyoming.

**Figure 1.** Relationship between plant growth and health and amount of nutrient available (Brady and Weil, 1999).

Q&A #1

How is plant analysis used as a diagnostic tool?

Plant analysis consists of testing nutrient concentrations in specific plant parts during specific growth stages (Jacobsen and Jasper, 1991). If nutrient concentrations in a sample are below or above an established sufficiency range, then the plant is deficient or in excess for that element. Plant analyses can be performed relatively quickly in the field using semi-quantitative test kits or more extensively in a laboratory (Havlin et al., 1999). As a diagnostic tool, plant analysis improves the chances of making a correct diagnosis and can be particularly useful in identifying hidden hunger or pseudo deficiencies.
is necessary to confirm nutrient stress. Precautions in identifying nutrient stress symptoms include the following:

1. **Many symptoms appear similar.** For instance, nitrogen (N) and sulfur (S) deficiency symptoms can be very alike, depending upon placement, growth stage, and severity of deficiencies.

2. **Multiple deficiencies and/or toxicities can occur at the same time.** More than one deficiency or toxicity can produce symptoms, or possibly a deficiency of one nutrient can induce the excessiveness of another (i.e., excessive P causing Zn deficiency).

3. **Crop species, and even some cultivars of the same species, differ in their ability to adapt to nutrient deficiencies and toxicities.** For example, corn is typically more sensitive to a Zn deficiency than barley (NM 7).

4. **Pseudo (false) deficiency symptoms (visual symptoms appearing similar to nutrient deficiency symptoms).** Potential factors causing pseudo deficiency include, but are not limited to, disease, drought, excess water, genetic abnormalities, herbicide and pesticide residues, insects, and soil compaction.

5. **Hidden hunger.** Plants may be nutrient deficient without showing visual clues.

6. **Field symptoms appear different than ‘ideal’ symptoms.** Many of the plants shown in this module as photographs were grown under controlled nutrient conditions, and deficiency/toxicity symptoms observed in the field may or may not appear as they do here. Experience and knowledge of field history are excellent aids in determining causes for nutrient stress.

In addition to the above precautions, visual observation is also limited by time. Between the time a plant is nutrient deficient (hidden hunger) and visual symptoms appear, crop health and productivity may be substantially reduced and corrective actions may or may not be effective. Therefore, regular soil or plant testing is recommended for the prevention and early diagnosis of nutrient stress.

If visual symptoms are observed, record which crop(s) are affected, their location with respect to topography, aspect, and soil conditions, a detailed description of symptoms, and time of season that the symptoms first appeared. Affected field locations can be marked and monitored over time using either flagging or GPS readings. This information will be useful in preventing nutrient stress for subsequent years.

---

**Q&A #2**

**I suspect a nutrient deficiency. How do I collect a plant sample for submission to an analytical laboratory?**

If you suspect nutrient stress, sample when symptoms first appear. To ensure quality results, samples should be taken from comparable locations (similar topography, aspect, and soil type) and at the same time of day. When testing samples for plant analysis, it is important to collect the part of the plant that will give the best indication of the nutrient status of the whole plant. The latest mature leaf is typically used, however, appropriate plant parts to test will vary with crop type and growth stage (see Appendix for additional resources). Collect numerous (20-30) subsamples of parts from plants that appear both abnormal and healthy, if possible. Subsamples may be combined for one sample. To gather plant samples, use a clean plastic or paper container (metal containers can contaminate samples). If the samples have soil, fertilizer, or spray residues on them, clean gently with a dry brush or with deionized or distilled water. Do not prolong washing because it can leach nutrients out of the tissue. Air-dry samples in the shade in either a paper bag or envelope. To avoid decomposition, do not use plastic bags or send fresh samples. When mailing samples to the laboratory, include type and variety of crop, current and past crop management practices, irrigation frequency (if applicable), soil type (if known), visual appearance of crops, and any insect or disease problems.
Diagnosing Nutrient Deficiencies

Common Deficiency Symptoms

A first step in diagnosing nutrient deficiencies is to describe what the symptoms look like. Each deficiency symptom must be related to some function of the nutrient in the plant (Havlin et al., 1999). The role of each essential nutrient in the plant is listed in Table 1 of NM 2. Symptoms caused by nutrient deficiencies are generally grouped into five categories: 1) stunted growth; 2) chlorosis; 3) interveinal chlorosis; 4) purplish-red coloring; and 5) necrosis. Stunting is a common symptom for many deficient nutrients due to their varied roles in the plant. For example, when nutrients involved in plant functions such as stem elongation, photosynthesis, and protein production are deficient, plant growth is typically slow and plants are small in stature. Chlorosis and interveinal chlorosis are found in plants deficient of nutrients necessary for photosynthesis and/or chlorophyll (green leaf pigment involved in photosynthesis) production. Chlorosis can result in either the entire plant or leaf turning light green to yellow, or appear more localized as white or yellow spotting. Interveinal chlorosis is the yellowing of leaf tissue between veins, with the veins themselves remaining green (Figure 2). Interveinal chlorosis occurs when some nutrients (B, Fe, magnesium (Mg), Mn, nickel (Ni), and Zn) are deficient. Purplish-red discolorations in plant stems and leaves are due to above normal levels of anthocyanin (a purple colored pigment) that can accumulate when plant functions are disrupted or stressed. This symptom can be particularly difficult to diagnose because cool temperatures, disease, drought, and even maturation of some plants can also cause anthocyanin to accumulate (Bennett, 1994). Certain plant cultivars may also exhibit this purple coloring. Necrosis generally happens in later stages of a deficiency and causes the parts of the plant first affected by the deficiency to brown and die. Since a number of nutrient deficiencies can produce similar symptoms, further evaluation of symptoms related to particular leaf patterns or locations on the plant will be needed to diagnose nutrient specific deficiencies. These specifics will be discussed in detail later in the module.

Figure 2. Interveinal chlorosis (Fe deficiency) (Bennett, 1993).
**Mobile and Immobile Nutrients**

Another initial step in identifying deficiency symptoms is to determine whether the deficiency is the result of a mobile or immobile nutrient based on where the symptom is appearing in the whole plant. Mobile nutrients are nutrients that are able to move out of older leaves to younger plant parts when supplies are inadequate. Mobile nutrients include N, P, K, Cl, Mg, and molybdenum (Mo). Because these nutrients are mobile, visual deficiencies will first occur in the older or lower leaves and effects can be either localized or generalized. In contrast, immobile nutrients (B, calcium (Ca), Cu, Fe, Mn, Ni, S, and Zn) are not able to move from one plant part to another and deficiency symptoms will initially occur in the younger or upper leaves and be localized. Zn is a partial exception to this as it is only somewhat immobile in the plant, causing Zn deficiency symptoms to initially appear on middle leaves and then affect both older and younger leaves as the deficiency develops.

**Identification key**

The ‘key’ on pages 6 and 7 can be used for identifying nutrient deficiencies based on common symptoms. The key consists of different alternative statements about plant structures and their appearance. If possible, it may be helpful to have a healthy plant on hand for comparison purposes. Beginning at the top of the key, read the first statement and determine whether the statement applies to the plant(s) being evaluated. If the statement describes the plant’s symptoms, proceed along the ‘YES’ arrow to the next statement. If not, follow the ‘NO’ arrow to an alternative statement. Continue this process until the probable nutrient responsible for the deficiency is identified. Although most descriptions in this key are generalized to accommodate common symptoms seen in various crops, bear in mind that deficiency symptoms differ among crop types and plant specific symptoms may not be listed (see text for detailed descriptions of deficiencies and Appendix for resources on specific crop symptoms).

**Mobile Nutrients**

**Nitrogen (N)**

Nitrogen is needed by plants for the production of proteins, nucleic acids (DNA and RNA), and chlorophyll. Symptoms of N deficiency are general chlorosis of lower leaves (light green to yellow), stunted and slow growth, and necrosis of older leaves in severe cases (Figure 3). N deficient plants will mature early and crop quality and yield are often reduced (Jones, 1998). In cereals, yellow discoloration from the leaf tip backward in the form of a “V” is common (Figure 4) (Jacobsen and Jasper, 1991). Insufficient amounts of N in cereals will also result in few tillers, slender stalks, short heads, and grains with low protein content. Leaf curling and small tubers are common in potatoes deficient of N. Fields deficient in N can be either uniform or patchy in appearance, depending on conditions favoring the deficiency.

![Figure 3. N deficiency in corn leaves (leaves on left are N deficient, leaf on right is normal). Yellow discolouration and stunted growth.](http://www.gov.on.ca/OMAFRA/english/environment/efp/infosheet_16.htm (Ontario Ministry of Agriculture and Food))

![Figure 4. N deficiency in barley. Top leaves are N deficient, bottom leaf is normal.](http://www.gov.on.ca/OMAFRA/english/environment/efp/infosheet_16.htm (Ontario Ministry of Agriculture and Food))
MOBILE NUTRIENTS

Older or lower leaves affected

YES

Effects mostly generalized; plants dark or light green

NO

Effects mostly localized; chlorosis with or without spotting

YES

Plants dark green, often developing purple or red color

NO

Chlorosis with interveinal chlorosis; leaves sometimes red or with dead spots

YES

NO

Plants light green with leaves light green or yellow; no necrotic spotting

NO

No interveinal chlorosis; chlorotic areas with a burning of leaf margins; spotting sometimes along leaf margins

YES

NO

Plants light green; necrotic spotting on leaves; pale leaves sometimes scorched, cupped or rolled

NO

No interveinal chlorosis; distinct chlorotic and necrotic lesions (spotting) with abrupt boundary between dead and live tissue

YES

* MOLYBDENUM (Mo)

* CHLORIDE (Cl)

*If symptoms don’t meet any of the key descriptions, either go back through the key another time or refer to text for more specific symptom descriptions.
Module 9 • Plant Nutrient Functions and Deficiency and Toxicity Symptoms

IMMOBILE NUTRIENTS

Newer or younger leaves affected; symptoms localized

Growing point (terminal bud) dies

NO

Growing point typically remains alive

YES

Young leaves of terminal bud become light green at bases; leaves become twisted and brittle and die back at growing point; chlorosis of young leaves

Young leaves of terminal bud typically hooked at first, finally turning brown and dying back

NO

YES

BORON (B)

NO

SULFUR (S)

NO

YES

MANGANESE (Mn)

NO

YES

IRON (Fe)

NO

YES

COPPER (Cu)

NO

YES

* ZINC (Zn)

(Common symptoms include chlorosis and interveinal chlorosis in younger leaves.)

NOTE: Since nickel (Ni) was only recently added as an essential nutrient, specific Ni deficiency symptoms are not well defined. Common symptoms include chlorosis and interveinal chlorosis in younger leaves.)
Phosphorus (P)

Plants require P for the development of ATP (energy), sugars, and nucleic acids. P deficiency symptoms are usually more noticeable in young plants, which have a greater relative demand for P than more mature plants (Grundon, 1987). Cool soils during the early growing season may also be a factor causing P deficiency. P deficient plants generally turn dark green (both leaves and stems) and appear stunted (Figure 5). Older leaves are affected first and may acquire a purplish discoloration due to the accumulation of sugars in P deficient plants which favor anthocyanin synthesis; in some cases, leaf tips will brown and die (Figure 6). Plants suffering from P deficiency appear weak and maturity is delayed. Leaf expansion and leaf surface area may also be inhibited, causing leaves to curl and be small. Wheat and small grains with P deficiency tend to be stressed and predisposed to root rot diseases, and some cultivars will turn red or purple. In alfalfa, an upward tilting of leaflets may occur. Potato P deficiency symptoms include leaves curling upward and tubers having brown internal specks, often radiating out from the core. P deficiency in corn is usually visual in young plants with leaves turning purple. From a field perspective, P deficiency is likely to occur on tops of ridges or other exposed areas that have highly eroded or weathered soils, or in areas that have been leveled, exposing subsoils high in calcium carbonate (CaCO₃). Crops grown in soils high in CaCO₃ are prone to P deficiency due to the precipitation of Ca-P insoluble minerals.

Potassium (K)

Potassium is utilized by plants in the activation of enzymes and co-enzymes (specialized proteins serving as catalysts and co-factors), photosynthesis, protein formation, and sugar transport. K deficiency does not immediately result in visible symptoms (hidden hunger). Initially, there is only a reduction in growth rate, with chlorosis and necrosis occurring in later stages (Mengel and Kirkby, 2001). Affected older leaves will show localized mottled or chlorotic areas with leaf burn at margins (Figure 7).

Figure 5. P deficiency in alfalfa (left) and normal alfalfa (right). P deficient leaf is dark green and stunted. (EB 43, 1991)

Figure 6. P deficiency in corn. Leaves are purplish (dark areas in photo) and tips are brown and necrotic.
Chlorotic symptoms typically begin on the leaf tip, but unlike the ‘V’ effect caused by N deficiency, K deficient chlorosis will advance along the leaf margins towards the base, usually leaving the midrib alive and green. As the deficiency progresses, the entire leaf will yellow. Small white or yellow necrotic spots may also develop, beginning along leaf margins (Figure 8). Another indication of K deficiency is reduced straw or stalk strength in small grains and corn, resulting in lodging problems, reduced disease resistance, and reduced winter-hardiness of perennial or winter annual crops (Jacobsen and Jasper, 1991). Produced grains will be low in protein and appear shriveled. In alfalfa, white spots will appear on leaf edges. Some cultivars, especially barley, develop excessive numbers of tillers when K is deficient. Due to K’s role in sugar accumulation, root crops (i.e., potatoes, sugarbeets) will have small tubers.

**Chloride (Cl)**

Chloride is required by the plant for leaf turgor and photosynthesis. Until recently, little information was documented on Cl deficiencies, as symptoms were often misdiagnosed as physiological leaf spot (Engel et al., 2001). However, recent studies have shown Cl deficiencies to exist in Montana, with visual symptoms observed in winter wheat and durum wheat cultivars (Engel et al., 1998; Engel et al., 2001). Plants with insufficient Cl concentrations show chlorotic and necrotic spotting along leaves with abrupt boundaries between dead and live tissue (Figure 9). Wilting of leaves at margins and highly branched root systems are also typical Cl deficient symptoms, found mainly in cereal crops (Mengel and Kirkby, 2001). Cl deficiencies are highly cultivar specific and can be easily mistaken for leaf diseases.

**Magnesium (Mg)**

Magnesium is the central molecule in chlorophyll and is an important co-factor for the production of ATP. As Mg concentrations are sufficient in most Montana and Wyoming soils, Mg deficiencies are not common. Symptoms of Mg deficiency include interveinal chlorosis and leaf margins becoming yellow or reddish-purple while the midrib remains green. In wheat, distinct mottling as yellowish-green patches will occur, and alfalfa leaves may curl and have reddish undersides. Leaves of Mg deficient sugarbeets and potatoes are stiff and brittle and veins are often twisted. Reduced Mg concentrations in wheat forage can lead to grass tetany (low blood serum Mg) in animals grazing on winter wheat (Jacobsen and Jasper, 1991).

Figure 7. K deficiency in corn. Older leaves are chlorotic and leaf edges are burned, but the midrib remains green. (From Bennett, 1993)

Figure 8. K deficient (left) and normal (right) trifoliates. White spotting occurring along leaf margins in deficient leaf.
**Molybdenum (Mo)**

Molybdenum is needed for enzyme activity in the plant and for nitrogen-fixation in legumes. Due to this interrelationship, Mo deficiency symptoms often resemble N deficiency symptoms with stunted growth and chlorosis occurring in legumes. Other symptoms of Mo deficiency include pale leaves that may be scorched, cupped, or rolled. Leaves may also appear thick or brittle, and will eventually wither, leaving only the midrib.

**Immobile Nutrients**

**Sulfur (S)**

As S is an essential constituent of certain amino acids and proteins, S deficiency results in the inhibition of protein and chlorophyll synthesis. S deficiency symptoms can be difficult to diagnose as effects can resemble symptoms of N and Mo deficiencies. In contrast to N or Mo deficiency, however, S deficiency symptoms initially occur in younger leaves, causing them to turn light green to yellow (chlorosis) (Figure 10). In later growth, the entire plant may be pale green. Characteristic spots or stripes are generally not displayed. Additionally, plants deficient in S tend to be spindly and small and stems are often thin.

**Boron (B)**

Primary functions of B in plants are related to cell wall formation and reproductive tissue. Plants suffering from B deficiency exhibit chlorotic young leaves and death of the main growing point (terminal bud). In addition to chlorosis, leaves may develop dark brown, irregular lesions that will progress to leaf necrosis in severe cases. Whitish-yellow spots may also form at the bases of leaves. Due to disturbances in cell wall growth, leaves and stems of B deficient plants will become brittle and distorted and leaf tips tend to thicken and curl. Affected plants will grow slowly and appear stunted as a result of shortened internodes (stem segment between points where leaves are attached). Because B tends to accumulate in reproductive tissues, flower buds may fail...
to form or are misshapen, and pollination and seed viability is usually poor in B deficient plants (Jacobsen and Jasper, 1991; Weise, 1993). In alfalfa and canola, B deficiency symptoms include rosetting (the clustering of leaves in crowded circles), yellowing of upper leaves, and poor flowering (Figure 11). A well-documented B deficiency in sugarbeets is crown and heart rot (Mengel and Kirkby, 2001). Along with stunted growth, symptoms include young leaves curling and turning brown or black in color. In later stages of the deficiency, the crown of the beet begins to rot and disease sets in, affecting the whole plant. The healthy part of the beet will be low in sugar.

Iron (Fe)

Iron plays an important role in plant respiratory and photosynthetic reactions. Fe deficiency reduces chlorophyll production and is characterized by interveinal chlorosis with a sharp distinction between veins and chlorotic areas in young leaves (Figure 12). As the deficiency develops, the entire leaf will become whitish-yellow and progress to necrosis. Slow plant growth also occurs. When viewed from a distance, Fe deficient fields exhibit irregularly shaped yellow areas, especially where the subsoil is exposed at the surface (Follett and Westfall, 1992).

Figure 11. Alfalfa with B deficiency; chlorosis of upper leaves and rosetting of leaves near base (From EB 43, 1991).

Figure 12. Progression of Fe deficiency in wheat leaves. Top leaf normal; middle leaves showing interveinal chlorosis with prominent green veins; and bottom leaf entirely chlorotic. (From Grundon, 1987).
Zinc (Zn)

Zinc is needed by plants for growth hormone production and is particularly important for internode elongation. As previously noted, Zn has intermediate mobility in the plant and symptoms will initially show up in middle leaves. Zn deficient leaves display interveinal chlorosis, especially midway between the margin and midrib, producing a striping effect; some mottling may also occur (Figure 13). Chlorotic areas can be pale green, yellow, or even white. Severe Zn deficiencies will cause leaves to turn gray-white and fall prematurely or die. Because Zn plays a prominent role in internode elongation, Zn deficient plants generally exhibit severe stunting. Flowering and seed set is also poor in affected plants. Crop specific symptoms include smaller leaf size in alfalfa, gray or bronze banding in cereal leaves, reduced tiller production in wheat and other small grains, and abnormal grain formation (Wiese, 1993). In cattle, Zn deficiencies in forage have been shown to reduce reproductive efficiency (Paterson, 2002). Zn deficiency generally does not affect fields uniformly and deficient areas usually occur where topsoil has been removed (Follet and Westfall, 1992).

Calcium (Ca)

Calcium is a component of plant cell walls and regulates cell wall construction. Ca deficiency is uncommon in many Montana and Wyoming areas due to the presence of calcium carbonates and gypsum in most agriculture soils. Insufficient Ca can cause young leaves to become distorted and turn abnormally dark green. Leaf tips often become dry or brittle and will eventually wither and die. Stems are weak and germination is poor.

Copper (Cu)

Copper is needed for chlorophyll production, respiration, and protein synthesis. Cu deficient plants display chlorosis in younger leaves, stunted growth, delayed maturity (excessively late tillering in grain crops), lodging, and, in some cases, melanosis (brown discoloration). In cereals, grain production and fill is often poor, and under severe deficiency, grain heads may not even form (Figure 14). Cu deficient plants are prone to increased disease, specifically ergot (a fungus causing reduced yield and grain quality); (Solberg et al., 1999). The onset of disease-caused symptoms may confound the identification of Cu deficient symptoms. Winter and spring wheat are the most sensitive crops to Cu deficiency (Solberg et al., 1999). In the field, Cu deficiency symptoms occur in

Figure 13. Zn deficiency displaying striped interveinal chlorosis.

Figure 14. Cu deficiency in wheat: severely affected (left), moderately affected (center), unaffected (right). Deficient wheat shows melanosis with poor grain production and fill.
irregular patches with melanosis being the most obvious symptom, particularly in wheat stands. Similar to Zn, forage that is deficient in Cu can cause a reduction in the reproductive efficiency of cattle (Paterson, 2002).

**Manganese (Mn)**
Chloroplasts (plant organelles where photosynthesis occurs) are the most sensitive of cell organelles to Mn deficiency (Mengel and Kirkby, 2001). As a result, a common symptom of Mn deficiency is interveinal chlorosis in young leaves (Figure 15). However, unlike Fe, there is no sharp distinction between veins and interveinal areas, but rather a more diffuse chlorotic effect. Two well known Mn deficiencies in arable crops are *grey speck* in oats and *marsh spot* in peas. White streak in wheat and interveinal brown spot in barley are also symptoms of Mn deficiency (Jacobsen and Jasper, 1991).

**Nickel (Ni)**
Nickel is required by plants for proper seed germination. Additionally, Ni is the metal component in urease, an enzyme that catalyzes the conversion of urea to ammonium (Havlin et al., 1999). Research has shown Ni to be beneficial for N metabolism in legumes and other plants in which ureides are important in metabolism (Gerendas et al., 1999). Though Ni deficiency symptoms are not well documented and believed to be non-existent in Montana and Wyoming, symptoms include chlorosis and interveinal chlorosis in young leaves that progresses to plant tissue necrosis. Other symptoms include poor seed germination and decreases in crop yield.

**Diagnosing Nutrient Toxicities**
As insufficient nutrient content can cause visual symptoms to occur in plants, so too can an excess. In Montana and Wyoming, macronutrient (N, P, and K) toxicities most often occur as a result of the over-application of fertilizers or manure. Secondary macronutrient (Ca, Mg, and S) toxicities are rare in this region and toxic effects on crop health have not been documented. Micronutrient toxicities can occur and are likely caused by over-application, using irrigation water high in micronutrients or salts, or in areas where micronutrient concentrations are abnormally high (i.e., areas exposed to mining activity or high metal minerals in subsoil). In addition, high amounts of non-essential elements such as arsenic (As), cadmium (Cd), and lead (Pb) can be directly toxic to plants and livestock or cause a nutrient imbalance in the plant, in which essential nutrient deficiencies or toxicities may possibly occur.

**N, P, and K**
Plants with excess N turn a deep green color and have delayed maturity. Due to N being involved in vegetative growth, excess N results in tall plants with weak stems, possibly causing lodging to occur. New growth will be succulent and plant transpiration high (low water use efficiency) (Jacobsen and Jasper, 1991). N toxicity is most evident under dry conditions and may cause a burning effect. Plants fertilized with ammonium (NH4\(^+\))-based fertilizers may exhibit NH4\(^+\) toxicity, indicated by reduced plant growth, lesions occurring on stems and roots, and leaf margins rolling downward.

Excess P indirectly affects plant growth by reducing Fe, Mn, and Zn uptake; thus, potentially causing deficiency symptoms of these nutrients to occur (see specific deficiency descriptions). Zn deficiency is most common under excess P conditions.

---

**Figure 15. Mn deficient wheat displaying interveinal chlorosis.**
Due to a cation imbalance, K toxicity can cause reduced uptake and subsequent deficiencies of Mg, and in some cases, Ca (see Mg and Ca deficiency descriptions).

**Micronutrients**

For many crops, the sufficiency range between deficiency and toxicity is narrower for micronutrients than macronutrients (Brady and Weil, 1999). This is particularly true for B in which the average sufficiency and toxicity ranges for various crops overlap one another: 10-200 ppm (sufficiency range) and 50-200 ppm (toxicity range) (Jones, 1998). B toxicity results in chlorosis followed by necrosis. Symptoms begin at the leaf tip and margins and spread toward the midrib. As the toxicity progresses, older leaves will appear scorched and fall prematurely. In sugarbeets, a yellow-tinted band will occur around leaf margins (Ulrich et al., 1993).

Other micronutrients causing potential toxicity symptoms include Cu, Mn, Mo, Ni, and Zn. Studies suggest excess Cu will displace Fe and other metals from physiologically important centers, causing chlorosis and other Fe deficiency symptoms, such as stunted growth, to appear (Mengel and Kirkby, 2001). Mn toxicity symptoms are generally characterized by blackish-brown or red spots on older leaves and an uneven distribution of chlorophyll, causing chlorosis and necrotic lesions on leaves. While Mo toxicity does not pose serious crop problems (crops may appear stunted with yellow-brown leaf discolorations), excess amounts of Mo in forage have been found to be toxic to livestock (Havlin et al., 1999). Similar to excess Cu, high Ni concentrations can cause Fe to be displaced. In turn, interveinal chlorosis may appear in new leaves of Ni toxic plants and growth may be stunted. Zn toxicity is not common, but can occur on very saline soils. Symptoms include leaves turning dark green, chlorosis, interveinal chlorosis, and a reduction in root growth and leaf expansion. Excess Zn may induce an Fe deficiency.

**Summary**

Nutrient deficiencies and toxicities cause crop health and productivity to decrease and may result in the appearance of unusual visual symptoms. Understanding each essential nutrient’s role and mobility in the plant can help in determining which nutrient is responsible for a deficiency or toxicity symptom. General deficiency symptoms include stunted growth, chlorosis, interveinal chlorosis, purple or red discoloration, and necrosis. Deficiencies of mobile nutrients first appear in older, lower leaves, whereas deficiencies of immobile nutrients will occur in younger, upper leaves. Nutrient toxicity is most often the result of over-application, with symptoms including abnormal growth (excessive or stunted), chlorosis, leaf discoloration, and necrotic spotting. When in excess, many nutrients will inhibit the uptake of other nutrients, thus potentially causing deficiency symptoms to occur as well.

As a diagnostic tool, visual observation can be limited by various factors, including hidden hunger and pseudo deficiencies, and soil or plant testing will be required to verify nutrient stress. Nonetheless, the evaluation of visual symptoms in the field is an inexpensive and quick method for detecting potential nutrient deficiencies or toxicities in crops, and learning to identify symptoms and their causes is an important skill for managing and correcting soil fertility and crop production problems.
